Abstract:

For the past 30 years Steve West, a scientist at Carlsbad Caverns, has been banding cave swallows and documenting data such as their weight, wind span, tail length, ect. The banding takes place on average a couple times a month, excluding winter due to their migration toward Mexico.

For most of our analysis we kept the adults and babies separated to obtain more accurate results. The newborn as well as matured birds are so similar in size and weight it is difficult to specify. The presence of freckles on their face and beak confirm they are a hatch year these freckles fade within their first year. To identify the bird's gender we look for a bru patch (a fatherless spot located on the birds chest which becomes visible when blown on). A bru patch signalizes that the bird has recently had eggs, which indicate it is a female. This is another category in which we sorted the birds during the analysis.

The data was first document by hand but was recently transferred into an excel spread sheet to be better analyzed. We took the data and categorized it by the tail length and right and left wing span. With this we found the maximum, minimum and average lengths. This analysis is the foundation for next year's project and will lead us to the answers of bigger questions.

Problem Definition:

Not much is known about the cave swallows at Carlsbad Caverns. Even though scientists have been banding them for so long they still have no hard evidence explaining what there average length, weight, wingspan is; how the weather affects them or the average life span, is still unknown. Furthermore, we already have the answers it's just a matter of finding them. Being in an excel document makes the data harder to analyze; a problem that we plan on solving in next year's project. However, based on the results we wanted to obtain we decided it would be more efficient to just leave the data in excel.

(Above you see an example photo of the hard copy bird data.)

Procedure:

Step 1

When beginning this project the first thing we did was verify all the data. When the data was being transferred into the excel document there were errors made and numbers copied incorrectly. We decided that for this year two years would be sufficient to obtain the results we were looking for. We chose the years at random: 1988 and 1995. This procedure took only a couple of days; with two students, one reading the numbers out of the book and the other checking it on the computer. When we would find a mistake the general rule was to go by what the book said but we were also able to ask Steve West to verify our conclusions.

Step 2

We went about the project by first organizing the data. Using the tools in excel we separated the babies from adults; the hatch year from after hatch year. Next we organized the date they were captured in order from earlier to later in the year.

Step 3

We went on to analyzing the data finding the average weight, left, right wing span and tail length from each day data was collected. This would help us understand the difference in weight and size between the adult birds and baby birds. To further identify the data we then went through all the information relating to the recaptured birds. Where we analyze the overall change from one month to the other, this made it easier to see the patters and cycles the cave swallows undergo annually.

Step 4

We charted all the results so they could be easily understood.

(Example of excel spreadsheet)

From this development we learned the average dimensions of a matured cave swallow. The average right wing span was 110.5 and the average left wing span was 110.2. The tail length was 32.9 and the weight 24.2. We also determine the average dimensions of a new born cave swallow. Average right wing span was 110.7 the left wing span was 110.5, the average tail length 32.9 and the average weight 24.03.

Conclusion

We have concluded that throughout the year cave swallows undergo an annual cycle of weight loss and molting. The main factor of these cycles is the climate changes from month to month and their migrating patterns. This project is laying down the foundation for a more extensive research and the development of a database. Our plans for this project is to create a database using the program MUMPS that will sort and analyze the data much more effectively and efficiently. We started with a small scale analysis in a excel workbook to obtain the basis of understanding what we would like next year's project to accomplish. References

Significant Achievement

Our biggest achievement in this project was laying down the foundation for a continuation next year. We now have a much better understanding of what we need to do to accomplish our goals. We are more familiar with the data and can easily understand it and have learned how to make useful connections.

Acknowledgements

We would like to give thanks to our teacher Creighton Edington who is always there and supporting us along the way. We would also like to thank our mentors Steve West who answered all our many questions and Dave Culp for giving us advice.
